Abstract— This efficient novel proposes the implementations of [RDH] Reversible data hiding technique with an adaptive high embedding capacity by using the [LSB] Least significant method to embed the data into the fused image. RDH can be used in important and sensitive areas like military applications where image secrecy is maintained. This method helps to hide or encrypt a data into an image with full embedding efficiency and the original content can be losslessly recovered and also includes the watermarking algorithm. The existing algorithm used generalized integer transformation [GIT] which was used for embedding process and generalized and adaptively embeds additional bits into different kinds of blocks. Thus, to enhance the security while encryption and decryption and to minimize the distortion and achieve security to the embedded data the RDH algorithm is used.

Keywords— Reversible data hiding, least significant bit, Discrete wavelet transform, data embedding.

1. Introduction

Steganography is the process to hide the communication and embedding a data into an image to ensure security and secure transmission of the data or information from sender to the authorized receiver. Reversible data hiding has attracted much interest over the past decades and intensively studied in the community of signal processing.

Using RDH, a message can be embedded into the original or host image, and the original message can be losslessly recovered from the original image. The technique of RDH is applied in some sensitive areas where there is no permanent change is allowed on the original or host signal. The existing RDH methods has different categories like compression based RDH ([1][3]), quantisation based RDH expansion based ([2][5][6]), Histogram based RDH ([4]) and integer transformation([7]-[10]) which explains the various implementations of RDH techniques. Also referred as invertible or lossless data hiding, RDH is to embed a piece of data which is to be hidden from a third party or from eaves dropping into a host signal to produce the marked one, and from which the original signal can be recovered after extracting the embedded information. The Discrete wavelet transform method is applied for the watermarking process and the data is embedded into the fused image. Both the image and data are encrypted using Least significant bit where the MSB bit of the data is embedded to the LSB of the image of the first pixel, this whole process is called as reversible data hiding. It then uses the AES for encryption of the data and the image and for the decryption process the data is recovered from the fused image using the key which is given to encrypt. Thus, the data and the image are recovered without any loss and full efficiency is obtained in the proposed paper.

3. Existing System

In the existing system more attention is paid to reversible data hiding (RDH) in encrypted images, since it maintains the excellent property that the original cover can be lossless recovered after embedded data is extracted while protecting the image content’s confidentiality. All previous methods embed data by reversibly vacating room from the encrypted images, which may be subject to some errors on data extraction/image restoration. Previous methods implement RDH

in encrypted images by vacating room after encryption, as opposed to which we proposed by reserving room before encryption.

3.1 Drawbacks of Existing System

- The hackers recover the embedding data in original image because the data placed in particular bit position which may be subject to some errors on data extraction and/or image restoration.
- Previous methods embed data by reversibly vacating room from the encrypted images, which may be subject to some errors on data extraction and/or image restoration.
- To attack the hidden data using original image because referred the key value.

4. Proposed System

This method can take advantage of all traditional RDH techniques for plain images and achieve excellent performance without loss of perfect secrecy. This method can achieve real reversibility, separate data extraction and greatly improvement on the quality of marked decrypted images. This method by reserving room before encryption with a traditional RDH algorithm, and thus it is easy for the data hider to reversibly embed data in the encrypted image. We can achieve real reversibility, that is, data extraction and image recovery are free of any error. The watermarking process and the embedding of data into the fused image is shown in figure 1.

5.2 Data Embedding

This model describes about the data embedding for secret sharing. Here data is embedded into a watermarked image. To embed a data into a watermarked image we use a LSB Steganography Technique which hides the data in the least significant bits of pixels color. For embedding data into a watermarked image first we need to convert both data and image into binary values. Then MSB bits of data will be embedded into the LSB bits of image. The resulting changes that are made to the least significant bits are too small to be recognized by the human.

5.3 Encryption Images

Encryption is a process which uses a finite set of instruction called an algorithm to convert original message, known as plaintext, into cipher text, its encrypted form.Cryptographic algorithms normally require a set of characters called a key to encrypt data. In encryption, we are using AES algorithm to hide the information from the data into the images. AES performs all its computations on bytes rather than bits. Hence, AES treats the 128 bits of a plaintext block as 16 bytes. These 16 bytes are arranged in four columns and four rows for processing as a matrix.

5.3.1 High-Level Description of the AES Algorithm

- Key Expansion—round keys are derived from the cipher key
- Initial Round:
  - AddRoundKey—each byte of the state is combined with the round key using bitwise xor
- ROUNDS
  - SubBytes—a non-linear substitution step where each byte is replaced with another according to a lookup table.
  - ShiftRows—a transposition step where each row of the state is shifted cyclically a certain number of steps.
    - MixColumns—a mixing operation which operates on the columns of the state, combining the four bytes in each column.
    - AddRoundKey
- Final Round (no MixColumns)
  - SubBytes
5.4 Decryption Images

In the decryption module the watermarked image which contains the data embedded and encrypted is decrypted by using the encryption key given in the AES algorithm. While decrypting the image and the data which is embedded is extracted separately with full efficiency and accuracy from the watermarked image. Thus, ensuring full secrecy while decrypting and achieve real reversibility that is, data extraction and image recovery are free of any error.

6. Experimental Results

In the existing system of using generalized integer transformation the hackers recover the embedding data in original image because the data placed in particular bit position. Previous methods embed data by reversibly vacating room from the encrypted images, which may be subject to some errors on data extraction and/or image restoration. To attack the hidden data using original image because referred the key value. The proposed system overcomes the above drawbacks and thus This method can achieve real reversibility, that is, data extraction and image recovery are free of any error. It is easy for the data hider to reversibly embed data in the encrypted image. This method can embed more than 10 times as large payloads for the same image quality as the previous methods.

7. Conclusion

A novel scheme for separable reversible data hiding in encrypted image is proposed, which consists of image encryption, data embedding and data-extraction or image-recovery phases. It encrypts the original uncompressed image using an encryption key. Although a data-hider does not know the original content, he can compress the least significant bits of the encrypted image using a data hiding key to create space to accommodate the additional data. With both the keys, the additional data and the original content can be recovered exploiting the spatial correlation and with efficient embedding and more data can also increases the capacity of the data to be embedded. In the future, a comprehensive combination of image encryption and data hiding compatible with lossy compression deserves further investigation.
